An extremal subharmonic function in non-archimedean potential theory

Małgorzata Stawiska

Abstract

We define an analog of the Leja-Siciak-Zaharjuta subharmonic extremal function for a proper subset $E$ of the Berkovich projective line $\mathbb{P}^1$ over a field with a non-archimedean absolute value, relative to a point $\zeta \notin E$. When $E$ is a compact set with positive capacity we prove that the upper semicontinuous regularization of this extremal function equals the Green function of $E$ relative to $\zeta$. As a separate result, we prove the Brelot-Cartan principle, under the additional assumption that the Berkovich topology is second countable.

1 Introduction

Potential theory on curves over a field $K$ complete with respect to a non-archimedean absolute value $| \cdot |$ has made substantial progress in recent years. Fundamental developments can be found in [20], [9], [3] and [23]. Nevertheless, some topics have been left unexplored, for instance extremal subharmonic functions associated with compact subsets. Such functions are well known in classical potential and pluripotential theory in $\mathbb{C}^N$, $N \geq 1$. Recall that in $\mathbb{C}$ (with the standard, archimedean absolute value) the Green function with pole at infinity of a compact subset $E$ can be proved to be equal to the so-called Leja extremal function (see [15], [16], [10]). In $\mathbb{C}^N$, $N > 1$, an analogous extremal function (Siciak-Zaharjuta extremal function, [21], [25], [22]), with plurisubharmonic functions replacing subharmonic ones, serves as a multivariate counterpart to the Green function. In this article we will work on the Berkovich projective line $\mathbb{P}^1$ over an algebraically closed complete field $K$. We will fix a point $\zeta \in \mathbb{P}^1$ (not necessarily equal to $\infty$) and define a class of subharmonic functions on $\mathbb{P}^1 \setminus \{\zeta\}$ with suitable behavior near $\zeta$. The supremum $Q_\zeta$ of this class can be treated as a non-archimedean analogue of the Leja-Siciak-Zaharjuta extremal function. We will further show that the Green function relative to a point $\zeta$ of a compact subset of $\mathbb{P}^1 \setminus \{\zeta\}$ of positive capacity (see subsection 2.3 for definitions) equals the upper semicontinuous regularization $Q_\zeta$ of $Q_\zeta$. Our approach is analytic and topological rather than geometric. In particular, we do not appeal to available results in the (already rich) non-archimedean pluripotential theory.

The paper is organized as follows: Throughout, we provide proofs only for statements that are new in the non-archimedean setting. When we explicitly state known results (without proofs), we do so for convenient reference. In Section 2 we gather the necessary background in potential theory on the Berkovich projective line, although we do not always present all details. This section is mainly a survey, but a few results therein are new in the non-archimedean setting. When we explicitly state known results (without proofs), we do so for convenient reference. However, Proposition 2.10 is a new result in the Berkovich setting.

2 Foundations of potential theory on the Berkovich projective line

This section recalls background notions and results developed by other researchers in potential theory on the Berkovich projective line (following mostly [3]), and so it can be skipped by readers familiar with the material. However, Proposition 2.10 is a new result in the Berkovich setting.
2.1 Berkovich projective line as a topological space

Let $K$ be an algebraically closed field (possibly of characteristic $>0$) that is complete with respect to a non-trivial and non-archimedean absolute value $|\cdot|$. The Berkovich projective line $P^1 = P^1(K)$ is the Berkovich analytification of the (classical) projective line $\mathbb{P}^1 = \mathbb{P}^1(K) = K \cup \{\infty\}$. Each point in $\mathbb{P}^1$ corresponds to an equivalence class of multiplicative seminorms on the polynomial ring $K[X, Y]$ extending the absolute value $|\cdot|$. The Berkovich upper half space is $H^1 = H^1(K) := \mathbb{P}^1 \setminus \mathbb{P}^1$. Taking into account the correspondences between points, seminorms and sequences of disks, the points in $\mathbb{P}^1$ can be further classified into four types, with $\mathbb{P}^1$ being the set of all points of type I. For some fields $K$ the set of points of type IV in $\mathbb{P}^1(K)$ may be empty. For further details see Chapter 2 of [3], or [13].

We will work only with the Berkovich topology on the Berkovich projective line (also called the weak topology). A basis for this topology is given in Proposition 2.7 in [3], while neighborhood bases for the four types of points are described in the discussion after Lemma 2.28 in that book. It follows that $\mathbb{P}^1$ with the Berkovich topology is locally connected. In particular, the connected components of open sets are open. We will use this property several times in this paper. Also, $\mathbb{P}^1$ with the Berkovich topology is uniquely arcwise connected ([3], Lemma 2.10).

Potential theory on the Berkovich projective line makes extensive use of the tree structure on $\mathbb{P}^1$. We will not present here the definition or general properties of this tree structure, even though it enters the formulation of some definitions and results we need. For details, we refer the reader to [3] or [13].

Definition 2.1. (i) (cf. p. 39, [3]) Let $(\zeta_1, \ldots, \zeta_n) \in H^1$ be a finite set of points. The finite subgraph with endpoints $(\zeta_1, \ldots, \zeta_n)$ is the intersection of all subtrees of $\mathbb{P}^1$ containing the set $(\zeta_1, \ldots, \zeta_n)$.

(ii) (cf. Definition 2.27, [3]) A simple domain is a domain $U \subset \mathbb{P}^1$ such that $\partial U$ is a nonempty finite set $(\zeta_1, \ldots, \zeta_n) \subset H^1$, where each $\zeta_i$ is of type II or III.

Proposition 2.1. (Corollary 7.11, [3]): If $U \subset \mathbb{P}^1$ is a domain, then $U$ can be exhausted by a sequence $V_1 \subset V_2 \subset \ldots$ of simple domains (i.e., simple domains with boundary points all of type II) such that $\bigcap V_n = \emptyset$ for all $n$.

Although the Berkovich topology on $\mathbb{P}^1$ is not metrizable in general, an analog of the chordal metric plays an important role in the potential theory. Namely, the spherical kernel, or the Hsia kernel $[x, y]_1$, on $\mathbb{P}^1$ with respect to the Gauss point $g$ (a distinguished point in the Berkovich unit disk) is the unique upper semicontinuous and separately continuous extension to $\mathbb{P}^1 \times \mathbb{P}^1$ of the chordal metric

$$[z, w] = \frac{|x_1y_2 - x_2y_1|}{\max(|x_1|, |y_1|) \max(|x_2|, |y_2|)}$$

defined for $z = (x_1 : y_1), w = (x_2 : y_2)$ in $\mathbb{P}^1 \times \mathbb{P}^1$. More generally, for each $\zeta \in \mathbb{P}^1$, the generalized Hsia kernel on $\mathbb{P}^1$ with respect to $\zeta$ is defined as

$$[x, y]_\zeta := [x, y]_1 / ([x, \zeta]_1 [y, \zeta]_1) \quad \text{on} \quad \mathbb{P}^1 \times \mathbb{P}^1.$$

Note that the kernel function $[x, y]_1$ satisfies the strong triangle inequality

$$[x, y]_\zeta \leq \max([x, z]_\zeta, [x, y]_\zeta) \quad \text{for any} \quad x, y, z \in \mathbb{P}^1.$$

Let us fix a $\zeta \in \mathbb{P}^1$. The generalized spherical kernel $[\cdot, \cdot]_1 = [\cdot, \cdot]_\zeta$ has the following properties: (cf. §4.3 in [3]):

(i) $0 \leq [x, y]_1 \leq 1$ (Formula 4.19)

(ii) (Proposition 4.7 (A), [3]) $[\cdot, \cdot]_1$ is continuous on the complement of the diagonal and at every $(x, x) \in \mathbb{P}^1 \times \mathbb{P}^1$;

(iii) (Proposition 4.7 (D), [3]) For each $a \in \mathbb{P}^1$ and $r \in \mathbb{R}$, the closed ball $B(a, r) := \{x \in \mathbb{P}^1 : |x - a| \leq r\}$ is connected and closed in the Berkovich topology. It is empty if $r < |a|$ and coincides with $B(b, r)$ for some $b \in \mathbb{P}^1$ if $r > |a|$. $B(a, r)$ is of type I or II and $B(a, r)$ is of type I or IV if $r = \text{diam}(a)$ and $a$ is of type II or III.

Finally, for an arbitrary function $f : \mathbb{P}^1 \to \mathbb{R}$ we define its upper semicontinuous regularization as $f^*(z) := \limsup_{y \to z} f(y)$.

2.2 Subharmonic functions

In this subsection we recall the basics on harmonic and subharmonic functions on the Berkovich projective line. We need to introduce the Laplacian on $\mathbb{P}^1$, but the available definitions are all quite involved, so we will only outline the theory, mostly following [3].

Let $\Gamma$ be a finite subgraph in $\mathbb{P}^1$ (viewed as a metric graph with the path distance $\rho$ on $\mathbb{P}^1$; see Section 2.7 in [3] for the definition of $\rho$).

Definition 2.2. (see Section 3.2 in [3]) A function $f : \Gamma \to \mathbb{R}$ is piecewise affine on $\Gamma$ if there is a set $S_f \subset \Gamma$ such that (i) $\Gamma \setminus S_f$ is a union of intervals, each of which has two distinct endpoints in $\Gamma$ and (ii) $f$ is affine on each interval in $\Gamma \setminus S_f$ with respect to its arclength parametrization. By $C_{PA}(\Gamma)$ we denote the class of continuous, piecewise affine real-valued functions on $\Gamma$.

For a point $x \in \mathbb{P}^1$ the set $\mathbb{P}^1 \setminus \{x\}$ does not have to be connected. The connected components of $\mathbb{P}^1 \setminus \{x\}$ can be identified with the tangent directions $\vec{v} \in T_x$ at $x$, defined as certain equivalence classes of paths emanating from $x$ (see Appendix B of [3] and the end of Section 3.1 in [3]). For any function $f \in C_{PA}(\Gamma)$, any $p \in \Gamma$ and any tangent direction $\vec{v}$ at $p$, the directional derivative $d_v f(p) := \lim_{t \to 0^+} \frac{f(p + t\vec{v}) - f(p)}{t}$, where $y$ is a representative path emanating from $p$, exists and is finite.
The Laplacian $\Delta$ is first defined for $f \in CPA(\Gamma)$, as

$$\Delta(f) := - \sum_{p \in \Gamma} \left( \sum_{x \in f(p)} d_x f(p) \right) \delta_x,$$

where $\delta_x$ denotes the Dirac measure at $p$. Then the class of functions $BDV(\Gamma)$ is defined (see Section 3.5 in [3]) and the Laplacian $\Delta_{\Gamma}(f)$ is defined for $f \in BDV(\Gamma)$ (Theorem 3.6 in [3]) extending the operator $\Delta$. That is, $\Delta_{\Gamma}(f) = \Delta(f)$ when $f \in CPA(\Gamma) \subset BDV(\Gamma)$.

Let $U \subset P^1$ be a domain. Using the natural retraction maps $r_{\Gamma}$ for each finite subgraph $\Gamma \subset U$ (see Section 2.5 in [3]), the Laplacian is extended to $\Delta_{\Gamma}(f)$ for functions $f \in BDV(U)$ (for the precise definitions, see Definitions 5.11 and 5.15 in [3]). Each such $\Delta_{\Gamma}(f)$ is a finite signed Borel measure on $U$. One further defines $\Delta_{\Gamma}(f) := \Delta_{\Gamma}(f)|_{V}$ and $\Delta_{\Gamma}(f) := \Delta_{\Gamma}(f)|_{U}$ for $f \in BDV(U)$.

Example (Example 5.19, [3]): Fix $\zeta \in P^1$ and $y \neq \zeta$. Let $f(x) := - \log |x - y|$. Then $f \in BDV(P^1)$ and $\Delta f = \delta_y(x) - \delta_{\zeta}(x)$.

Let $U$ be an open set in $P^1$.

**Definition 2.3.** (Definition 8.1, [3]) (i) A function $f : U \to [-\infty, \infty)$ is subharmonic in $U$ if for each $x \in U$ there is a domain $V_x \subset U$ with $x \in V_x$ such that $f \in BDV(V_x)$, $\Delta_{V_x}(f) \leq 0$, $f$ is upper semicontinuous in $V_x$, and for each $z \in V_x \cap P^1$, $f(z) = \limsup_{y \to z, y \neq z} f(y)$.

(ii) A function $f : U \to \mathbb{R}$ is harmonic in $U$ if and only if $f$ and $-f$ are subharmonic in $U$.

Many properties of harmonic and subharmonic functions known from the classical potential theory hold also in the Berkovich setting. We now list those which will be used later in the paper.

**Proposition 2.2.** (Maximum principle; Proposition 8.14 (B) in [3]) Let $U \subset P^1$ be a domain and let $f$ be a subharmonic function in $U$. Then, if $M \in \mathbb{R}$ is such that, for each $y \in \partial U$, $\limsup_{x \to y} f(x) \leq M$, then $f(x) \leq M$ for all $x \in U$.

**Proposition 2.3.** (Proposition 8.26 (E) in [3]) Let $U \subset P^1$ be an open set and let $(f_a)_{a \in A}$ be a net of subharmonic functions in $U$ which is locally uniformly bounded from above. Put $f(x) = \sup_{a \in A} f_a(x)$. Then $f$ is subharmonic in $U$ and $f^+(x) = f(x)$ for all $x \in U \cap H^1$.

**Proposition 2.4.** (Harnack’s inequality; Lemma 8.33, [3]) Let $U \subset P^1$ be a domain. Then for each $x_0 \in U$ and each compact set $X \subset U$ there is a constant $C = C(X_0, X)$ such that for each function which is harmonic and nonnegative in $U$, each $x \in X$ satisfies

$$\frac{1}{C} \cdot h(x_0) \leq h(x) \leq C \cdot h(x_0).$$

The default topology on the set $SH(U)$ of subharmonic functions in a domain $U \subset P^1$ is that of pointwise convergence on $U \cap H^1$. The space $M^+(U)$ of positive locally finite Borel measures on $U$ can be given the following topology: a net of measures $(\mu_a)_{a \in A}$ in $M^+(U)$ converges (weakly) to a measure $\mu \in M^+(U)$ if and only if $\int f \mu_a \to \int f \mu$ for all $f \in C_c(U)$. Here $C_c(U)$ is the space of all continuous functions $f : U \to \mathbb{R}$ for which there exists a compact subset $X_f \subset U$ such that $f|_{U \setminus X_f} \equiv 0$. The following continuity result will be used.

**Proposition 2.5.** (Theorem 8.44, [3]) Let $SH(U)$ and $M^+(U)$ be the topological spaces as described above. Then the operator $\Delta_{\Gamma} : SH(U) \to M^+(U)$ is continuous.

Here we also recall, in a general framework, a useful consequence of weak convergence.

**Proposition 2.6.** (cf. Formula (5.1.15) in [1] for sequences of positive Radon measures in metric spaces) Let $X$ be a locally compact Hausdorff space, $f$ be a nonnegative lower semicontinuous function on $X$, and $(\mu_a)_{a \in A}$ be a net of positive Radon measures on $X$ converging weakly to a positive Radon measure $\mu$ on $X$. Then

$$\liminf_a \int f \mu_a \geq \int f \mu.$$

**Proof.** By Proposition A.3 in [3],

$$\int f \mu = \sup \left\{ \int g \mu : g \in C_c(X), 0 \leq g \leq f \right\},$$

where the class $C_c$ is defined as above. Then

$$\liminf_a \int f \mu_a \geq \sup_{g \in C_c(X), 0 \leq g \leq f} \liminf_a \int g \mu_a = \sup_{g \in C_c(X), 0 \leq g \leq f} \int g \mu = \int f \mu. \qed$$

In the literature on subharmonic functions in the Euclidean space various (related) results are referred to as a "Hartogs lemma". Some of them have their non-archimedean counterparts.
Proposition 2.7. (Proposition 8.54 in [3]) Let $U \subset \mathbb{P}^1$ be a domain and let $(g_n)$ be a sequence of functions subharmonic in $U$. Suppose that the functions $g_n$ are uniformly bounded from above in $U$. Then one of the following holds:

(i) there is a subsequence $(g_{n_k})$ which converges uniformly to $-\infty$ on each compact subset of $U$, or

(ii) there is a subsequence $(g_{n_k})$ and a function $G$ subharmonic in $U$ such that $g_{n_k}$ converge pointwise to $G$ in $U \cap H^1$ and such that for each continuous function $f : U \to \mathbb{R}$ and each compact subset $X \subset U$,

$$\limsup_{k \to \infty} \left( \sup_{z \in X} (g_{n_k}(z) - f(z)) \right) \leq \sup_{z \in X} (G(z) - f(z)).$$

Corollary 2.8. (cf. Theorem 1.31 and Corollary 1.32 in [17] in the Euclidean case; see also [14], Theorem 2.6.4)) Let $U \subset \mathbb{P}^1$ be a domain and let $(g_n)$ be a sequence of functions subharmonic in $U$ uniformly bounded from above in $U$. Suppose that the functions $g_n$ converge pointwise on $U \cap H^1$ to a function $G$ subharmonic in $U$.

(i) Suppose further that for some compact set $X \subset U$ there is a constant $C = C(X)$ such that $(\sup_{n \to \infty} g_n(x))^+ \leq C$ on $X$. Then for every $\epsilon > 0$ there is an $n_0 = n_0(\epsilon, X)$ such that for every $\geq n_0$ and every $x \in X$ we have $g_n(x) \leq C + \epsilon$. (ii) More generally, under the above assumptions, let $F$ be a function continuous on $X$ such that $(\sup_{n \to \infty} g_n(x))^+ \leq F(x)$ on $X$. Then for every $\epsilon > 0$ there is an $n_0 = n_0(\epsilon, X)$ such that for every $\geq n_0$ and every $x \in X$ we have $g_n(x) \leq F(x) + \epsilon$.

Proof. For (i), let $c_\epsilon := \sup_{x \in X} g_n(x)$ and let $\epsilon > 0$. By the inequality from part (ii) of Proposition 2.7, $(\sup_{n \to \infty} g_n(x))^+ \leq C$ on $X$ with $C := \sup_{x \in X} G(z)$. Take an $n_0$ such that for every $\geq n_0$, $c_\epsilon \leq \sup_{n \to \infty} g_n(x)$. Then $c_\epsilon \leq C + \epsilon$. Part (ii) follows from (i) by observing that $F$ is uniformly continuous on $X$ (taking into account the unique uniform structure on $\mathbb{P}^1$ compatible with the Berkovich topology; see Appendix A.9, [3]).

Here are some results on convergence of harmonic functions in open subsets of $\mathbb{P}^1$.

Proposition 2.9. (Proposition 7.31, [3]) Let $U$ be an open subset of $\mathbb{P}^1$. Suppose $f_1, f_2, \ldots$ are harmonic on $U$ and converge pointwise to a function $f : U \to \mathbb{R}$. Then $f$ is harmonic in $U$ and the $f_i$ converge uniformly to $f$ on compact subsets of $U$.

Proposition 7.34 in [3] gives a non-archimedean Harnack principle for a sequence $0 \leq h_1 \leq h_2 \leq \ldots$ of harmonic functions on a domain $\Omega \subset \mathbb{P}^1$. Theorem 4.7.2 in [24] is slightly more general, since it does not require the sequence to be non-negative. A similar result is Proposition 3.1.2 in [23], while Proposition 3.1.3 and Corollary 3.3.10 in [23] are equicontinuity results for locally uniformly bounded families of harmonic functions. Here we offer an even more general variant of the Harnack principle, for a family $F$ of harmonic functions on a domain $\Omega \subset \mathbb{P}^1$ that is locally uniformly bounded from below in $\Omega$ but not necessarily uniformly so from below in $\Omega$, countable or increasing. This is a new result in the non-archimedean setting.

Proposition 2.10. (cf. [2], Theorem 1.5.11 in the classical case) Let $\Omega \subset \mathbb{P}^1$ be a domain and let $F$ be a family of harmonic functions on $\Omega$ which is locally uniformly bounded from below. Then either $\sup F \equiv +\infty$ in $\Omega$ or $F$ is uniformly bounded and uniformly equicontinuous on every compact subset $E \subset \Omega$.

Proof. If $\sup F \not\equiv +\infty$, then we can fix an $x_0 \in \Omega$ such that $\sup E(x_0) < +\infty$. Let $E \subset \Omega$ be a compact set and let $V \subset \mathbb{P}^1$ be a domain such that $E \cup \{x_0\} \subset V \subset \overline{\Omega} \cap \Omega$. The family $F$ is uniformly bounded from below on $\overline{V}$, so without loss of generality we can assume that all functions in $F$ are positive on $\overline{V}$. By Proposition 2.4, there is a constant $C = C(E, x_0)$ such that for every $f \in F$ and every $x \in E$, $0 < f(x) \leq C$. Hence $F$ is uniformly bounded on $E$. Further, the right side of the inequality in Proposition 2.4 is the same as Axiom III, of [18]. By the Theorem of [18], the family $F$ of positive functions is equicontinuous in a compact neighborhood of $x_0$.

2.3 The Green function

In this section, we fix the base $q > 1$ of logarithms which occur in the definition of potentials. Typically this is done so that the absolute value $| \cdot |$ coincides with the modulus of the Haar measure on the additive group of $K$. When $K = \mathbb{C}_p$, $p$ prime, one takes $q = p$ (see Example 6.4 in [3]).

Definition 2.4. ([3], Section 6.3) Fix $z \in \mathbb{P}^1$ and let $v$ be a positive measure on $\mathbb{P}^1$. The potential of $v$ with respect to $z$ is the function

$$u_v(x, z) = \int x \log|x, y| d\nu(y).$$

Remark (Example 8.8, [3]): If $v$ is a probability measure on $\mathbb{P}^1$ and $z \notin \text{supp} \, v$, then the potential $u_v(\cdot; z)$ is strongly subharmonic in $\mathbb{P}^1 \setminus \text{supp} \, v$, while $-u_v(\cdot; z)$ is strongly subharmonic in $\mathbb{P}^1 \setminus \{z\}$.

Proposition 2.11. (Theorem 8.38, [3]: Riesz decomposition theorem) Let $V$ be a simple subdomain of an open set $U \subset \mathbb{P}^1$. Fix $z \in \mathbb{P}^1 \setminus \overline{V}$. Suppose $f$ is subharmonic in $U$ and let $v$ be the positive measure $v = -\Delta_v(f)$. Then there is a function $h_v$ which is continuous in $\overline{V}$, harmonic in $V$ and such that $f(z) = h_v(z) - u_v(x, z)$ for all $z \in V$.

Let now $E \subset \mathbb{P}^1$ be a compact subset such that $z \notin E$ and let $v$ be a probability measure with support contained in $E$. Following Section 6.1, [3], we define a few basic notions.

Definition 2.5. The energy of $v$ with respect to $z$ is

$$I_z(v) = \int_E u_v(x, z) d\nu(x).$$
Varying \( \nu \) over all probability measure with support in \( E \) we further define

**Definition 2.6.** The Robin constant of \( E \) with respect to \( \zeta \) is

\[
V_\zeta(E) = \inf_{\nu} I_\zeta(\nu)
\]

and the (logarithmic) capacity of \( E \) is

\[
\text{cap}_\zeta(E) = q^{-V_\zeta(E)}.
\]

Remark: Unlike in the classical setting, there are finite subsets of Berkovich line with positive capacity: in fact, for every \( a \in H^1 \) and \( \zeta \neq a \), \( \text{cap}_\zeta(\{a\}) = \text{diam}_\zeta(\{a\}) > 0 \).

Remark: Other capacity notions can be defined for subsets of \( P^1 \) (see Section 6.4 of [3]). While they coincide for compact subsets (Theorem 6.24 in [3]), they may differ for non-compact subsets (Remark 6.25 in [3]).

**Proposition 2.12.** (Corollary 6.17, [3]): Let \( \{e_n\}_{n \in \mathbb{N}} \) be a countable collection of Borel subsets of \( P^1 \setminus \{\zeta\} \) such that each \( e_n \) has capacity 0. Let \( e = \bigcup_{n \in \mathbb{N}} e_n \). Then \( e \) has capacity 0.

If \( E \) is compact and \( \text{cap}_\zeta(E) > 0 \), there is a (unique) probability measure \( \mu_\zeta \) supported on \( E \) for which \( V_\zeta(E) = I_\zeta(\mu_\zeta) \) (Propositions 6.6 and 7.21 in [3]).

**Definition 2.7.** The measure \( \mu_\zeta \) is called the equilibrium measure of \( E \) with respect to \( \zeta \). If \( \zeta \notin E \), the Green function of \( E \) with respect to \( \zeta \) is

\[
G(z, \zeta, E) := V_\zeta(E) - u_{\mu_\zeta}(z, \zeta).
\]

We recall here several known properties of the Green function of a compact set \( E \subset P^1 \setminus \{\zeta\} \) with positive capacity. Let \( D_\zeta \) denote the connected component of \( P^1 \setminus E \) containing \( \zeta \).

**Proposition 2.13.** (Proposition 7.37, [3])

(i) \( G(z, \zeta, E) \) is finite for every \( z \in P^1 \setminus \{\zeta\} \).

(ii) \( G(z, \zeta, E) \geq 0 \) for every \( z \in P^1 \) and \( G(z, \zeta, E) > 0 \) for every \( z \in D_\zeta \).

(iii) \( G(z, \zeta, E) = 0 \) on \( P^1 \setminus D_\zeta \) except on a (possibly empty) set \( e \subset D_\zeta \) of capacity zero.

(iv) \( G(z, \zeta, E) \) is continuous on \( P^1 \setminus e \).

(v) \( G(z, \zeta, E) \) is subharmonic on \( P^1 \setminus \{\zeta\} \) and (strongly) harmonic on \( D_\zeta \setminus \{\zeta\} \). For every \( a \neq \zeta \), \( G(z, \zeta, E) - \log|z-a|_\zeta \) extends to a function harmonic in a neighborhood of \( \zeta \).

(vi) \( G(z, \zeta, E) = G(z, \zeta) \), \( P^1 \setminus \{\zeta\} \) and \( \zeta \) is continuous on \( D_\zeta \).

(vii) If \( E_1 \subset E_2 \) are two sets of positive capacity, then \( G(z, \zeta, E_1) \geq G(z, \zeta, E_2) \).

### 3 Brelot-Cartan principle

In this section we will work under an additional topological assumption, namely that of the second countability of the Berkovich topology. This is restrictive but still reasonable. On one hand, when there exists a countable base of open sets for the Berkovich topology on \( P^1 \), the underlying field is necessarily separable as a topological space. The precise conditions characterizing such fields are not known, but as observed in [19], separability may fail even if the residue field and the value group are both countable. On the other hand, for the fields \( \mathbb{Q}_p \), \( p \) prime (which are separable; see discussion before Corollary 1.20 in [3]), such a countable base exist. For some results related to countability of the topologies on \( P^1 \) see [8] and [12]. The second countability of the Berkovich topology allows us to apply the following lemma:

**Lemma 3.1.** (Choquet topological lemma; for this formulation and its proof see [6], A.VIII.3) Let \( \{u_i\}_{i \in I} \) be a family of functions from a second countable Hausdorff space to \( [-\infty, +\infty] \). For a \( J \subset I \), define \( u' = \sup_{i \in J} u_i \). Then there is a countable subset \( J' \subset J \) such that \( (u')^{(J')} = (u)^{(J')} \), where \( v^{(J)}(x) = \lim sup_{y \to x} v(y) \).

Using the Choquet topological lemma we can prove the Brelot-Cartan principle. It was first proved in [4] (in connection with Dirichlet regularity) and [5] (in a more general context). Our formulation and the general strategy of proof follows the classical version as presented in [2], Theorem 5.7.1 (ii) and (iii).

**Theorem 3.2.** Let \( \Omega \subset P^1 \) be a domain and \( \{u_i\}_{i \in I} \) be a family of functions subharmonic on \( \Omega \) which is locally uniformly bounded from above. Let \( u = \sup_{i \in I} u_i \). Then the set \( \{x \in \Omega : u(x) < u'(x)\} \) has capacity zero.

**Proof.** By Proposition 2.1, every domain different from \( P^1 \) can be exhausted by a sequence \( V_1 \subset V_2 \subset \ldots \) of (strict) simple domains such that \( V_\infty \subset V_{n+1} \subset \Omega \) for each \( n \). Since \( u(x) = u'(x) \) in \( \Omega \cap H^1 \), it is enough to prove that for any simple domain \( V \subset \Omega \) any compact subset of \( \{x \in V : u(x) < u'(x)\} \) has capacity zero. So let us fix a point \( \zeta \notin \Omega \) and take a simple domain \( V \) such that \( \overline{V} \subset \Omega \). By Lemma 3.1 there is a sequence \( (u_n) \subset \{u_i\}_{i \in I} \) such that \( u_\zeta = v_\zeta \), where \( v_\zeta = \sup_{n \in \mathbb{N}} u_n \). By Proposition 2.3, \( v_\zeta \) is subharmonic. Defining \( v_\zeta = \max\{u_1, \ldots, u_n\} \) we get an increasing sequence \( (v_\zeta) \) of subharmonic functions with limit \( v \). By Proposition 2.5, the positive measures \( \mu_\zeta := -\Delta v_\zeta \) converge weakly to the positive bounded measure \( \mu := -\Delta v \). Consider the potentials \( p_{\mu_\zeta}(z, \zeta) = -\log|z-w| \frac{d\mu_\zeta}{d\mu}(w) \). Since the function \(-\log|z-w|_\zeta \) is lower semicontinuous and bounded below on \( \overline{V} \), we have by Proposition 2.6 that \( \liminf_{n \to \infty} p_{\mu_\zeta} \geq p_{\mu} \) on \( V \).

By Proposition 2.11, for every \( n \) there exists a function \( h_n \) continuous on \( \overline{V} \) and harmonic on \( V \) such that \( v_\zeta = h_n - p_{\mu_\zeta} \). The functions \( h_n, n=1, 2, \ldots \) are locally uniformly bounded below on \( V \). Indeed, \( h_n \geq v_1 + p_{\mu_\zeta} \) for every \( n \). If \( C \) is a compact subset of
V and x ∈ C, then there is an N > 0 such that for every n ≥ N, h_n(x) ≥ v_1(x) + \lim inf_{p \to \infty} P_{h_n} - \frac{1}{2} ≥ (v_1)_n(x) + p_n(x) - \frac{1}{2}. Taking infimum over x ∈ C on both sides of the inequality, we get h_n ≥ inf_{V}(v_1) + inf_{F} \mu(C) - \frac{1}{2} on C for every n ≥ N, and hence a common lower bound on C for all h_n. By Proposition 2.10, there exists a subsequence (h_n) that converges locally uniformly to a (continuous) harmonic function h on V. Since v_n → v and h_n → h, then also p_n converges as k → ∞ and lim_{k→∞} P_{p_n} ≥ p_n on V.

We have v(x) = h(x) = \lim_{k→∞} p_{p_n}(x) ≤ h(x) - p_n(x) = v^*(x) in V, so it is enough to prove that the set E = \{x ∈ V : \lim_{k→∞} P_{p_n}(x) > p_n(x)\} has capacity zero. Suppose there is a compact subset F ⊂ E such that capF > 0. Let v be the equilibrium measure on F with respect to ζ. Then, by continuity of p_n on F ⊂ F with capF > 0, portmanente theorem and Fatou's lemma,

\[ \int_{F} p_{n} \, d\nu = \int_{F} p \, d\mu = \lim_{k→∞} \int_{F} p_k \, d\mu_k = \lim_{k→∞} \int_{F} p_{\mu_k} \, d\nu ≥ \int_{F} \lim_{k→∞} p_{\mu_k} \, d\nu \]

which is a contradiction. Hence E has capacity zero. Since v ≤ u and u^* = v^*, the set \{x : u(x) < u^*(x)\} is a subset of \{x : v(x) < v^*(x)\} and also has capacity zero.

Remark 1. In Proposition 8.26 (E) of [3] it was shown that u(x) = u^*(x) for every x ∈ H^1. The Brelot-Cartan principle in the Berkovich setting refines this relation, since nonempty subsets of H^1 have positive capacity.

4 The extremal function

4.1 An upper envelope

Fix a point ζ ∈ P^1. Define the following:

Definition 4.1.

\[ L = \mathcal{L}(ζ) := \{ u : u \text{ is subharmonic in } P^1 \setminus \{ζ\}, ∀u ≠ ζ u - log[z, a]_ζ \text{ extends to a function subharmonic in } P^1 \setminus \{a\} \}. \]

Definition 4.2. Let ζ and L(ζ) be as in Definition 4.1 and let E ⊆ P^1 \ {ζ} be nonempty. Define

\[ S \mapsto \mathcal{Q}_E (S) := sup \{ u(S) : u ∈ L, u|E ≤ 0 \}. \]

We call Q_E the L-extremal function (relative to ζ) associated to E.

Proposition 4.1. If E has positive capacity, then the class of functions defining Q_E is not empty.

Proof. If E ⊂ H^1, then the Green function G(ζ, E, ζ) of E relative to ζ is in L and G(ζ, E, ζ) = 0 on E. If E ∩ P^1 ≠ ∅, take a point a ∈ E ∩ P^1 and r ≥ sup_{x∈E}[z, a]. The function \{log[z, a]_ζ - log r\} = max{log[z, a]_ζ - log r, 0} is then in L, and it is non-positive on E.

The following property holds (for the classical analog, see [14], Corollary 5.1.2).

Proposition 4.2. If E_1 ⊂ E_2 ⊂ ... is a sequence of nonempty sets in P^1 \ {ζ} and E = \bigcap_{n=0}^{∞} E_n, then Q_E = \lim_{n→∞} Q_{E_n}.

Proof. Since Q_{E_1} ≤ ... ≤ Q_{E_n} ≤ ... ≤ Q_{E}, the limit lim_{n→∞} Q_{E_n} exists and does not exceed Q_E. Conversely, for an u ∈ L and an ε > 0 the open set \{u < ε\} is a neighborhood of E containing E for all sufficiently large n. Hence for those n, u - ε ≤ Q_{E_n} ≤ lim_{n→∞} Q_{E_n}.

Since ε was arbitrary, Q_E ≤ lim_{n→∞} Q_{E_n}.

Having fixed a point ζ ∈ P^1, we can compute an example of the function Q. Let a ∈ P^1 \ {ζ}, r ∈ (diam_{ζ}(a), diam_{ζ}(ζ)) and let B_r = B(a, r) \ {ζ} := \{z : [z, a]_ζ ≤ r\}. When a ∈ H^1, the bounds on r guarantee that B_r ≠ ∅ and B_r ≠ P^1.

Proposition 4.3. (cf. Property 2.6 in [22], Example 5.1.1 in [14], Théorème 3.6 in [26])

\[ \mathcal{Q}_B(z) = max\{log[z, a]_ζ - log r, 0\} = (log[z, a]_ζ - log r)^+. \]

Proof. Recall that, by Formula 5 in Section 5.2 of [20], the function on the right-hand side is the Green function of B_r. Arguing like in Proposition 4.1, we get that \{log[z, a]_ζ - log r\} ≤ \mathcal{Q}_B(z). In the reverse direction, let v ∈ C = \mathcal{L}(B_r, ζ). The function v(z) - log[z, a]_ζ + log r extends to a subharmonic function in A_r = P^1 \ B_r. By Remark 4.13 in [3], the set A_r is the connected component of P^1 \ {ζ} containing ζ, where x is the unique point on the path from a to ζ with diam_{ζ}(x) = r. Moreover, v(z) - log[z, a]_ζ + log r ≤ 0 on ∂B_r = ∂A_r, and so by the maximum principle v(z) - log[z, a]_ζ + log r ≤ 0 in A_r. Hence on P^1 \ {ζ} we have v(z) ≤ log[z, a]_ζ - log r and finally \mathcal{Q}_B(z) ≤ (log[z, a]_ζ - log r)^+.

The behavior of locally uniformly bounded families in L is analogous to what happens in C^∞. Namely, the following holds:

Proposition 4.4. (cf. [14], Proposition 5.2.1; [22], Theorem 3.5; [26], Lemma 3.10) Let \Omega ⊂ \mathcal{L}(ζ) be a non-empty family, let u = sup{v : v ∈ Ω} and let Ω be a connected component of P^1 \ Ω. If the set Ω = \{z ∈ Ω : u(z) < +∞\} has nonzero capacity, then the family Ω is locally uniformly bounded from above in Ω. If moreover Ω is locally uniformly bounded from above in P^1 \ Ω, then u^* ∈ Ω.
Proof. Suppose $\mathcal{U}$ is not locally uniformly bounded in $\Omega$. Then there exists a simple domain $V \subset \Omega$ and a sequence $(u_j)$ in $\mathcal{U}$ such that $m_j := \sup_{\partial V} u_j \geq 2^j$ for every $j \in \mathbb{N}$. We have $u_j \leq m_j + Q_\Omega$ on $\Omega \setminus \{\zeta\}$ for every $j \geq 1$. Fix a simple domain $V'$ such that $\overline{V} \subset V' \subset \Omega$. The family $(u_j - m_j)_{j \in \mathbb{N}}$ is uniformly bounded in $V'$. We claim that there exists an $x_0 \in V'$ such that $\limsup_{j \to \infty} u_j(x_0) > -\infty$. Suppose to the contrary that $\limsup_{j \to \infty} u_j \equiv -\infty$ in $V'$. Then $\limsup_{j \to \infty} \exp(u_j(x_0) - m_j) \equiv 0$ in $V'$, so $\lim_{j \to \infty} \exp(x_0(x) - m_j) = 0$ in $V'$. Note that all functions $\exp(u_j(x_0) - m_j)$ are subharmonic (by Corollary 8.29 in [3]) and have an uniform upper bound in $V'$. Hence, by Proposition 2.7 and Corollary 2.8, there exists a subsequence $(u_{j_k})$ and an $n_0 \geq 1$ such that $\sup_{V'} \exp(u_{j_k}(x_0) - m_{j_k}) \leq 1/2$ for every $n \geq n_0$. Taking natural logarithm of both sides of this inequality we get a contradiction with the definition of $m_j$. The claim allows us (passing to a subsequence of $u_j$ if necessary) to fix an $x_0 \in \Omega$ and an $\varepsilon > 0$ such that $u_j(x_0) - m_j > \log \varepsilon$ for every $j \geq 1$. Define next

$$
 v(x) = \sum_{j=1}^{\infty} \frac{1}{2^j} (u_j(x) - m_j)
$$

for every $x \in \Omega \setminus \{\zeta\}$. Note that on every simple subdomain of the domain the function $v$ is the limit of a uniformly convergent sequence of subharmonic functions. Therefore (by Proposition 8.26 (C) in [3]) $v$ is subharmonic in $\Omega$. If $x \in A \cap \Omega$, then $\sup u_j(x) < +\infty$, and so $v(x) = -\infty$, while $v(x_0) \geq \log \varepsilon - \infty$. Hence, by Corollary 8.40 in [3], $A \cap \Omega$ has capacity zero.

Now, if the family $\mathcal{U}$ is locally uniformly bounded in $\Omega \setminus \{\zeta\}$, then by Proposition 2.3, $u'$ is subharmonic on $\Omega \setminus \{\zeta\}$. Let us fix arbitrarily an $a \in \Omega \setminus \{\zeta\}$ and a simple subdomain $W$ of $\Omega \setminus \{\zeta\}$. Let $h$ be a harmonic function in $W$ such that $u' - \log[a] < h$ on $\partial W$. Then for every $y \in \mathcal{U}$, $v' - \log[a] \leq h$ on $\partial W$. By Theorem 8.19 in [3] or Corollary 3.1.12 in [23], $v' - \log[a] \leq h$ in $W$ (when $\zeta \in W$, we consider the subharmonic extension of $v' - \log[a]$, to $W$), so $u' - \log[a] + h < W$. Since $\log[a] + h$ is continuous as a function of $z \in W$, we also have $u' \leq \log[a] + h$ in $W$ and so (again by Theorem 8.19 in [3]), $u' - \log[a] + h$ extends as a subharmonic function in $W$. Hence $u' \in L$.

\[ \square \]

**Corollary 4.5.** (cf. Corollary 3.9 in [22], Theorem 5.2.4 in [14]) For a nonempty $E \subset \Omega \setminus \{\zeta\}$ the following are equivalent:

(i) There exists a function $v$ subharmonic in $\Omega \setminus \{\zeta\}$ such that $E \subset \{x \mid v(x) = -\infty\}$.

(ii) The capacity of $E$ equals zero.

(iii) There exists a function $w \in L(\Omega)$ such that $E \subset \{x : w(x) = -\infty\}$.

Proof. The implication (iii) $\Rightarrow$ (i) is obvious and (i) $\Rightarrow$ (ii) is Corollary 8.40 in [3]. Applying Proposition 4.4 to the family $\mathcal{U} = \{w \in L : w_{|E} \leq 0\}$ yields (ii) $\Rightarrow$ (iii).

Remark: For a compact set $F \subset \Omega \setminus \{\zeta\}$ one can also directly construct a function $w$ of class $L(\Omega)$ such that $F \subset \{w = -\infty\}$. For $N \in \mathbb{N}$ let $P_N$ denote a pseudopolynomial $P_N(z) = \prod_{j=1}^{N} [a_j, a_j] ;$ with $a_1, ..., a_N \in F$. For every $k \in \mathbb{N}$, let us pick a real number $p_k \geq 0$ and $a_1^{(k)}, ..., a_N^{(k)} \in F$ such that $\sum_{k=1}^{\infty} p_k = 1$ and the function

$$
 w(z) := \sum_{k=1}^{\infty} p_k \left( \frac{1}{N_k} \log P_{N_k}(z) \right)
$$

is the negative of an Evans function for $F$ (see Lemma 7.18 in [3]). It is easy to see that $w \in L(\Omega)$.

Let $E \subset \Omega \setminus \{\zeta\}$ be an arbitrary compact with positive capacity and let $G(\zeta, E, F) := V_{E} - p_{\zeta}(\cdot)$ be the Green function with pole at $\zeta$ (see subsection 2.3). Our goal is to show that the equality $Q_{E} = G(\zeta, E, F)$ holds. From Proposition 4.3 we already know it for a class of sets $B_\zeta$. Now we will establish it in another important special case, that of the complement of a simple domain. Note that in these special cases $Q_{E} = Q_{\zeta}$.

**Proposition 4.6.** Let $V \subset \Omega$ be a simple domain such that $\zeta \in V$. Then $Q_{\partial V}(\cdot) = G(\zeta, P_{V \setminus V}, \partial V)$. In particular, the function $Q_{\partial V}(\cdot)$ is continuous in $\Omega \setminus \{\zeta\}$ and strongly harmonic in $V \setminus \{\zeta\}$.

Proof. For $z \in \Omega \setminus \{\zeta\}$, $Q_{\partial V}(z) \leq 0 = G(z, P_{\partial V \setminus V}, \zeta)$. Fix an $x \notin \overline{V}$. By Proposition 4.4, the function $Q_{\partial V}(z) - \log[a]$ has subharmonic extension to $\Omega$. Note that $Q_{\partial V}(z) = Q_{\partial V}(\cdot)$ on $\partial V$, since $\partial V \subset H^1$. Then $Q_{\partial V}(z) - \log[a] - G(z, P_{\partial V \setminus V}, \zeta) - \log[a] \leq 0$ on $\partial V$. Using the maximum principle we get that $Q_{\partial V}(z) \leq G(z, P_{\partial V \setminus V}, \zeta) \in V \setminus \{\zeta\}$. In the other direction, $G(z, P_{\partial V \setminus V}, \zeta) \leq L_{\partial V \setminus V} \setminus \zeta$ and $G(z, P_{\partial V \setminus V}, \zeta) \leq 0$. Hence in $\Omega \setminus \{\zeta\}$ we have $Q_{\partial V}(\cdot) = G(\zeta, P_{\partial V \setminus V}, \zeta)$.

Now we are ready to prove the general case.

**Theorem 4.7.** For an arbitrary compact subset $E \subset \Omega \setminus \{\zeta\}$ of positive capacity, $G(\zeta, E, E) = Q_{E}(\cdot)$ in $\Omega \setminus \{\zeta\}$.

Proof. Note first that $Q_{\partial D}(\cdot) = Q_E$, where $D_{\zeta}$ is the connected component of $\Omega \setminus E$ containing $\zeta$. Indeed, let $U$ be a connected component of $\Omega \setminus E$ not containing $\zeta$ and let $\zeta \in E(\Omega, E)$. By the maximum principle, $u \leq 0$ on $U$. Hence $u \leq 0$ on $P_{D_{\zeta}}$, which shows that $Q_{\partial D_{\zeta}} \geq Q_{E}$. (The other inequality is obvious). Since $G(\zeta, E, E) = G(\zeta, P_{\Omega \setminus D_{\zeta}})$, it is thus enough to establish the equality in the theorem for sets $E = \partial \Omega$ of positive capacity, where $D \subset \Omega$ is a domain containing $\zeta$.

For such a domain $D$ consider an exhaustion by simple domains $V_{1} \subset V_{2} \subset ...$ such that $\overline{V_{k}} \subset V_{k+1} \subset ...$ and let $F_{\zeta} := P_{\Omega \setminus V_{k}}$. Then, by Proposition 4.6, $G_{\zeta} := G(\zeta, F_{\zeta}) = Q_{F_{\zeta}}$. By Proposition 4.2, $Q_{E} = \lim_{k \to \infty} G_{\zeta} \leq G(\zeta, E)$.
It remains to prove that $G(z, \zeta, E) \leq Q^*_E$ in $P^1 \setminus \{\zeta\}$. Let $e \in \partial D$ be the (possibly empty) set of capacity zero such that $G(z, \zeta, E) > 0$ for all $z \in e$. Then $G(z, \zeta, E) \leq Q_{E(e)}$. By Corollary 4.5, there exists a function $\nu \in \mathcal{L}$ such that $e \in K := \{z \in P^1 \setminus \{\zeta\} : \nu(z) = \infty\}$. Without loss of generality we can assume that $\nu \leq 0$ on $e$. Let $u \in L$ be such that $u \leq 0$ on $e$ and let $e \to 0$ be arbitrary. Then $u + \nu \in Q_{E(e)}$. Letting $e \to 0$ we get that $Q_e \leq Q_{E(e)}$ (and hence $Q_e = Q_{E(e)}$) outside the set $K$, which has zero capacity. Hence also $G(z, \zeta, E) \leq Q_e$ for every $z \in K$. By Remark 7.38 in [3], we have

$$G(z, \zeta, E) = \limsup_{H \to y \to \zeta} G(y, \zeta, E) = \limsup_{y \to \zeta} Q_E(y) \leq \limsup_{x \to \zeta} Q_E(x) = Q^*_E(z),$$

which completes the proof. □

**Corollary 4.8.** $Q_e = R_e := \sup\{u \in L' : u|_{L'_e} \leq 0\}$, where

$L' := \{u : u \text{ is subharmonic in } P^1 \setminus \{\zeta\}, \forall a \neq \zeta \ u - \log|z, a|_L \text{ extends to a function harmonic in } P^1 \setminus \{a\}\}.$

**Proof.** With the notation as in the proof of Theorem 4.7,

$$Q_e = \sup_n G_n \leq R_e.$$

The other inequality is obvious. □

### 4.2 Comparison with the classical case

Fix a $\zeta \in P^1$ and let $u \in \mathcal{L} = \mathcal{L}(\zeta)$. For an arbitrary $a \neq \zeta$, rewrite

$$u(z) - \log|z, a|_L = u(z) - \log\left(\frac{|z, a|_L}{|z, \zeta|_L[a, \zeta|_L]\right).$$

As $z \to \zeta$, we see (by continuity of the Hsia kernel $[z, y]_L$ near $\zeta \neq a$) that $\limsup_{z \to \zeta} u(z) - \log|z, a|_L = \limsup_{z \to \zeta} (u(z) + \log|z, \zeta|_L)$. The limit superior exists, since $u(z) - \log|z, a|_L$ extends to a function which is subharmonic, in particular upper semicontinuous, in a neighborhood of $\zeta$.

Recall that the spherical kernel $[x, y]_L$ is an extension of the chordal metric from $P^1(K) \times P^1(K)$ to $P^1 \times P^1$. Consider now the field $\mathcal{C}$ of complex numbers with the standard (archimedean) absolute value and the point $\zeta = \infty \in P^1(\mathcal{C})$. The chordal distance $[z, \zeta]_{\mathcal{C}}$ equals $\frac{1}{\sqrt{1 + |z|^2}}$ for $z \in \mathcal{C}$. The class $\mathcal{C}$ of all functions $u$ subharmonic in $\mathcal{C}$ and such that $u(z) \leq \frac{1}{2}\log(1 + |z|^2) + C_u$ with a constant $C_u$ dependent only on $u$ is the Lelong class $\mathcal{L}_C$ on $\mathcal{C}$ (an analogous class of plurisubharmonic functions can be defined on $C^n$ for $n > 1$). Here we use the natural logarithm. Each difference $u(z) - \frac{1}{2}\log(1 + |z|^2)$ extends to an $\omega$-subharmonic function $v$ on $P^1(\mathcal{C})$ (where $\omega$ is the Fujibay-Study form) by taking $v(\infty) = \limsup_{z \to \zeta} u(z) - \frac{1}{2}\log(1 + |z|^2)$, and the extensions yield a natural 1-to-1 correspondence between the Lelong class and the class of $\omega$-subharmonic functions. This viewpoint on Lelong classes was introduced in [11] and it helped launch systematic (and successful) study of pluripotential theory on compact (complex) Kähler manifolds. Our class $\mathcal{L}$ is a non-archimedean analog of the Lelong class, and similarly the class $\mathcal{L}'$ is an analog of the class $\mathcal{L}'_C = \{u \in \mathcal{L}_C : u(z) - \frac{1}{2}\log(1 + |z|^2) = O(1)\text{ as } z \to \infty\}.

Some extremal functions associated with compact subsets of $\mathcal{C}$ are well known because of their usefulness in approximation theory. In [15], F. Leja introduced the following extremal function:

Let $E \subset \mathcal{C}$ be a compact set. For an array $a^{(n)} = (a_0^{(n)}, \ldots, a_n^{(n)})$, $n = 2, 3, \ldots$ of points in $\partial E$ (with all $a_i^{(n)}$, $i = 0, \ldots, n$ pairwise distinct) define the quantities

$$M(a^{(n)}) := \max_{0 \leq j < k \leq n} \left| a_j^{(n)} - a_k^{(n)} \right|.$$

Consider an array of Fekete extremal points in $\partial E$, that is, an array $b^{(n)} = (b_0^{(n)}, \ldots, b_n^{(n)})$, $n = 1, 2, \ldots$ such that $M(b^{(n)}) = \max_{d(0)} M(a^{(n)})$ for every $n \geq 2$. In each row $b^{(n)}$ order the points so that $|\Delta_j(b_0, \ldots, b_n)| \leq |\Delta_j(b_0, \ldots, b_n)|, j = 1, 2, \ldots, n$, where

$$\Delta_j(b_0, \ldots, b_n) := (b_j - b_0)(b_j - b_1)\cdots(b_j - b_{j+1})\cdots(b_j - b_n), j = 0, 1, \ldots, n.$$

Let $L_n$ be the Lagrange interpolating polynomial $L_n(z) = \prod_{0 \leq j < k \leq n} \frac{(z - b_j)(z - b_k)}{(b_k - b_j)}$. The function

$$L(z) := \lim_{n \to \infty} \frac{1}{n} \log|L_n(z)|$$

is well defined for all $z \in \mathcal{C}$.

Under the assumption that $E$ is a union of (non-degenerate) continua, Leja also proved that $L$ equals the Green function $G(\cdot, \infty, E)$ for $E$ with pole at infinity. In [10], J. Górski (a student of Leja) proved the equality $L(z) = G(\cdot, \infty, E)$ for an arbitrary compact $E$ with positive capacity. In [21], J. Siciak (another student of Leja) defined an analog of the Leja extremal function for compact subsets of $C^N$. Another extremal function for a compact subset of $C^N$, $N \geq 1$, was defined in [25] as

$$V_E(z) := \sup\{u \in \mathcal{L} : u|_{L_E} \leq 0\},$$
where (for \( N > 2 \)) \( L \) is the class of all plurisubharmonic functions \( u \) with logarithmic growth, \( u(z) \leq \frac{1}{z} \log(1 + ||z||^2) + C_\eta \) (the Lelong class). Proofs that \( V_\eta = L(\cdot, E) \) (different ones) were given in [25] for \( E \) with \( V_\eta \) continuous, and in [22] (Theorem 4.12) for an arbitrary non-polar compact \( E \) (see also [14], Theorem 5.1.7 and, in an even more general setting of algebraic varieties embedded in \( \mathbb{C}^n \), [26], Théorème 5.1). It was observed without proof in both [25] (beginning of Section 4) and [22] that \( V_\eta(\cdot) = G(\cdot, \infty, E) \) when \( n = 1 \).

Note that using our method of proof of Theorem 4.7 one can prove directly that \( V_\eta^*(\cdot) = G(\cdot, \infty, E) \) in \( \mathbb{C} \), without relying on the separate equalities of each of these functions with the function \( L(\cdot, E) \). As before, we consider \( G(\cdot, \infty, E) \) as the Robin constant of the set \( E \) minus the equilibrium potential. We can also assume without loss of generality that \( \mathbb{C} \setminus E \) is connected. Recall that in proving the equality \( G_\eta = Q_\eta^* \) in the non-archimedean case we took advantage of the possibility of exhausting a domain with a sequence of subdomains whose boundaries do not contain sets of zero capacity (simple domains). There are no such subdomains in \( \mathbb{C} \) with the standard absolute value, where each point has zero logarithmic capacity. Hence different auxiliary results must be used. First, for a general unbounded domain \( D \subset \mathbb{C} \) we can take (as in [10]) an exhaustion of \( D \) by domains \( D_\eta \), \( n \geq 1 \), such that, for every \( n \), \( D_\eta \subset D_{n+1} \), \( G(\cdot, \infty, \mathbb{C} \setminus D_\eta) = 0 \) and \( D_\eta \to D \) in the sense of Carathéodory convergence of domains. Then \( G(\cdot, \infty, \mathbb{C} \setminus D) = \lim_{\eta \to \infty} G(\cdot, \infty, \mathbb{C} \setminus D_\eta) = \lim_{\eta \to \infty} V_\eta^{\ast}(\cdot) \). Second, we need a way to compare \( V_\eta^{\ast} \) with \( V_\eta^* \) for every \( E \) bounded and \( F \) of zero capacity. In fact, the equality \( V_\eta^{\ast} = V_\eta^* \) holds in \( \mathbb{C}^n \), \( N \geq 1 \): see Proposition 3.11 in [22] or Corollary 5.2.5 in [14]. With these tools in place, the arguments of Theorem 4.7 go through in the archimedean case.

Finally, let us note that other characterizations of the Green function as the extremal function relative to a class of functions with certain growth are also available in the classical theory. For example, see [6], formula 1.13 (18.1) in the logarithmic potential case; see further [6], Theorem 1.VII.2 in the Newtonian potential case in \( \mathbb{R}^n \), \( n > 2 \).
